Gestational Diabetes, Day by Day

Your gestational diabetes diagnosis, explained calmly: results, blood sugar checks, plates, birth and the test after.

Welcome

Perhaps a midwife or an obstetrician has just said the words "gestational diabetes" and the rest of the appointment went by in a blur. Perhaps you are sitting with a new meter and a leaflet, wondering how to fit finger pricks, meal planning and a growing baby into the same week. Whatever brought you here, take a breath. You are not alone, you have not failed, and there is a great deal you can do.

Gestational diabetes is one of the most common conditions of pregnancy. The Centers for Disease Control and Prevention (CDC) says that every year 5% to 9% of pregnancies in the United States are affected. Diabetes UK estimates that it affects one in eight women during pregnancy. The NHS puts it simply: most women with gestational diabetes "have otherwise normal pregnancies with healthy babies", and the risks "can be reduced if the condition is detected early and well managed".

That second sentence is what this book is about. It gathers what the official health bodies of the United States and the United Kingdom say, and turns it into plain explanations, tables, checklists and pages to fill in: a 14-day blood sugar log, a 7-day food and feelings journal, questions for your team, and a hospital bag and birth plan for a pregnancy with diabetes.

What this book is, and what it is not

This book is information, not medical advice. It cannot examine you, it does not know your results or your history, and it never replaces your obstetrician, your midwife, your diabetes team, your dietitian or your family doctor. When something worries you, the right move is always to call them. You will read that sentence many times in these pages, on purpose.

You will not find any medicine doses here, no personal blood sugar targets, and no meal plan with prescribed portions. Those belong to your team, because they depend on you. You will find what the guidelines say, explained clearly; examples of official targets so that the numbers on your meter make sense; general principles for building plates and snacks, always to check with your dietitian; the warning signs, with the numbers to call; and honest chapters on feelings, partners and life after the birth.

> **Every pregnancy deserves respect.**
>
> Gestational diabetes can happen to anyone: slim or not, young or older, first baby or fourth, with a healthy lifestyle or a hectic one. Every way of feeding your baby and every way of giving birth is a real and good way. This book does not judge, and neither should anyone else.

US and UK: same condition, different words

The biology is the same in Texas and in Manchester, but the tests, the units and the names of the people who care for you differ. Here is a quick key.

You may hear (US)	You may hear (UK)	What it means
OB-GYN, maternal-fetal medicine specialist	Obstetrician, consultant	The doctor who oversees your pregnancy
Diabetes care and education specialist	Diabetes specialist nurse or midwife	The person who teaches you to test and adjust
Registered dietitian nutritionist (RDN)	Dietitian	The expert who builds your eating plan with you
mg/dL (milligrams per deciliter)	mmol/L (millimoles per liter)	Units for blood sugar readings
Glucose challenge test, OGTT	Oral glucose tolerance test (OGTT)	The tests used to diagnose gestational diabetes
911	999 (or 112)	Emergency number
Your OB office or labor and delivery triage	Maternity unit or triage line, NHS 111	Who to call for urgent advice

The US Preventive Services Task Force (USPSTF) gives the conversion between the two units: to convert a reading in mg/dL to mmol/L, multiply by 0.0555. You do not need to do the arithmetic: the tables in this book show each country's figures in its own unit.

How to use this book

You do not need to read it in order. If you are waiting for a test, start with Chapters 2 and 3. If you have just been diagnosed, go to Chapter 4, then Chapter 5 (testing your blood sugar) and Chapter 6 (your plate). If you are in the third trimester, read Chapters 9 and 10 with your partner and fill in the birth plan in Chapter 15. After the birth, Chapter 11 tells you which test to ask for and when. Keep Chapter 15, your pages to fill in, on the fridge or in your bag.

> A note on words. Health bodies use different words: woman, mother, mom, mum, pregnant person. We mostly say "you". Whatever your family looks like, whether you are on your own, with a partner, a wife, a husband or co-parents, whether you conceived naturally, with IVF or a donor, this book is for you.

Chapter 1. Gestational diabetes in plain words

What it is

The NHS defines gestational diabetes as "high blood sugar (glucose) that develops during pregnancy and usually disappears after giving birth". It "can happen at any stage of pregnancy, but is more common in the second or third trimester".

To understand why, it helps to know what insulin does. Insulin is a hormone made by the pancreas. After you eat, the sugar from your food passes into your blood, and insulin acts like a key that lets that sugar into your cells, where it is used for energy. When there is not enough insulin, or when the body responds to it less well, sugar stays in the blood and the level rises.

Pregnancy changes this balance on purpose. The American College of Obstetricians and Gynecologists (ACOG) explains that "higher levels of pregnancy hormones can interfere with insulin". The American Diabetes Association (ADA) adds that the placenta's hormones, "which support the baby's growth, can sometimes block the mother's insulin, leading to insulin resistance". The National Institute of Diabetes and Digestive and Kidney Diseases (NIDDK) says that "all pregnant women have some insulin resistance during late pregnancy". Most bodies answer by making more insulin. In some women, the pancreas cannot keep up, and blood sugar rises: that is gestational diabetes.

> **The short version.**
> Your placenta makes hormones that help your baby grow. Those hormones make insulin work less well. Your body needs to make extra insulin to compensate, and right now it cannot make quite enough. Treatment helps your body bridge that gap until the placenta is delivered.

What it is not

It is not your fault. Diabetes UK answers the question many women ask in the middle of the night: "Gestational diabetes is not directly caused by consuming too much sugar." Weight, age, family history, ethnic background and the hormones of pregnancy all play a part, and many of these are out of anyone's control. ACOG states clearly that gestational diabetes "also can develop in women who have no risk factors".

It is not a sign that you have done something wrong in your pregnancy, and it does not mean your baby will be unwell. It is a condition that responds to care.

It is not, in most cases, a lifelong condition. ACOG says that gestational diabetes "goes away after childbirth", though it leaves a higher risk of diabetes later in life (Chapter 11).

When diabetes is found in pregnancy but started before

Sometimes a test in pregnancy reveals diabetes that was already there, unnoticed, before the pregnancy began. ACOG notes that "some women who develop GD may have had mild diabetes before pregnancy and not known it", and that for them diabetes "does not go away after pregnancy". This is one reason why the National Institute for Health and Care Excellence (NICE) in the UK recommends measuring HbA1c (a blood test that reflects average blood sugar over recent months) when gestational diabetes is diagnosed, "to identify women who may have pre-existing type 2 diabetes". If this applies to you, your team will explain the next steps; the care is very similar, and starting it early is what matters.

Does it cause symptoms?

Usually not. NIDDK says gestational diabetes "often has no symptoms, or they may be mild, such as being thirstier than normal or having to urinate more often". The World Health Organization (WHO) notes that it "is diagnosed through prenatal screening, rather than through reported symptoms". That is why testing matters.

The NHS lists symptoms that some women may notice if their blood sugar gets too high:

- increased thirst
- needing to pee more often than usual
- a dry mouth
- tiredness
- blurred eyesight
- genital itching or thrush

The NHS adds that "some of these symptoms are common during pregnancy and are not necessarily a sign of gestational diabetes". If one of them worries you, mention it to your midwife or doctor.

Why treatment matters, in one table

Gestational diabetes matters because extra sugar in your blood crosses the placenta. ACOG explains: "her body passes more sugar to her fetus than it needs. With too much sugar, her fetus can gain a lot of weight." Most of the possible problems follow from that.

Possible problem	What it means	Source
A baby growing larger than usual	Can make birth more difficult and make induction or a cesarean more likely	NHS
Polyhydramnios	Too much amniotic fluid around the baby	NHS
Pre-eclampsia	A condition causing high blood pressure in pregnancy	NHS, ACOG
Premature birth	Birth before 37 weeks	NHS

Possible problem	What it means	Source
Low blood sugar or jaundice in the baby after birth	May need treatment in hospital	NHS
Stillbirth	The NHS says this is rare	NHS
Type 2 diabetes later for you	A higher risk, which can be reduced	NHS, ACOG

Is this normal?

Reading a list like this can be frightening. Remember what the NHS says alongside it: most women with gestational diabetes have otherwise normal pregnancies with healthy babies, and the risks can be reduced with early detection and good management. The list explains why your team watches closely; it does not predict what will happen to you.

What the research shows about treatment

Two large clinical trials changed how doctors see gestational diabetes, and they are worth knowing because they show that what you do each day really counts.

In the ACHOIS trial (Crowther and colleagues, New England Journal of Medicine, 2005), 1,000 women with gestational diabetes were randomly assigned either to dietary advice, blood glucose monitoring and insulin as needed, or to routine care. Serious complications for the babies (defined as death, shoulder dystocia, bone fracture and nerve palsy) occurred in 1% of the treated group and 4% of the routine-care group. The treated group had more inductions of labor (39% versus 29%) and more babies admitted to the nursery (71% versus 61%), but similar cesarean rates. At three months after birth, the women who had been treated had lower rates of depression.

In a US trial of mild gestational diabetes (Landon and colleagues, New England Journal of Medicine, 2009), 958 women were randomly assigned to treatment (diet, self-monitoring and insulin if needed) or usual care. Treatment did not significantly change the main combined outcome, but it reduced the proportion of large-for-gestational-age babies (7.1% versus 14.5%), shoulder dystocia (1.5% versus 4.0%), cesarean delivery (26.9% versus 33.8%) and pre-eclampsia or gestational hypertension combined (8.6% versus 13.6%).

In other words: the testing, the walking after meals, the careful plates and, if needed, the medicines are not busywork. They are what the evidence supports.

End of the sample

Thank you for reading this far. We hope these first pages already feel useful, and that you can see how the rest of the book is built: clear steps, pages to fill in, sources you can check.

The full book has 58 pages.
